

Case 8

Signalment:

A 6 year old Standardbred gelding.

History:

Four week history of weight loss and depression

Physical Examination:

The horse was not able to trot. Some swelling of the left fore fetlock was present, but palpation failed to identify a specific cause of the lameness

Available Study:

Bone scan images of both fore fetlocks and radiographs of the same region.

L

This is an anteroposterior (AP) radiograph of a knee joint. Two large, white, lobulated masses are visible on the femoral condyles, representing a bilateral femoral condylar lesion. The masses are well-defined and have a cauliflower-like appearance. The joint space is preserved, and there is no evidence of acute fracture or dislocation. A white letter 'L' is located in the bottom right corner of the image, indicating the left knee.
